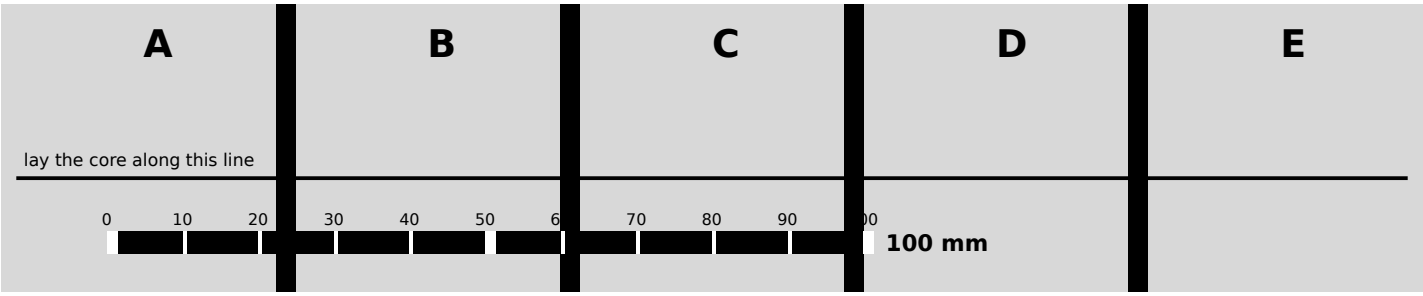
# AGE CORE PHOTO CARD

Print at 100% - do NOT scale to fit - matte paper - black only is fine - align the ruler edge of this sheet with the table edge



## OPTICAL CALIBRATION - same plane as the core

finest resolvable bar group

2 1 0.7 0.5 0.35

bar period, mm - the finest group that is still sharp tells the app the real limit

grey step wedge

white reference

## HOW TO USE

1 Place the core in ONE bay, along the black axis line. One photo per bay.
2 Keep the core, the 100 mm bar and the bar target in one plane - same height off the table. That is what tells the app the real focus.
3 For a broken or short core, photograph only the bays you can fill.
4 Use diffuse light. If you can, cross-polarise: a polarising filter on the lens and the lamp turned 90 degrees away. It cancels the sheen off the raised grain, which is what hides the ring boundaries.
5 Fill the frame with the core. Unused width costs you pixels per ring.
6 Note the bay letter, so a partial count can be tied to a section.
7 Measure the 100 mm bar with a ruler after the first print and enter the TRUE length in the app. Printers commonly shrink by 5-10% and the app cannot detect that from anything printed on the same sheet.
8 Shoot RAW if you can. It has 64x the tonal depth of a JPEG, and the ring boundaries are close to the JPEG noise floor.

put a bank card here to check the print scale

ID-1 is 85.60 x 53.98 mm. If your print shrank, this outline will be smaller than the card and you will see it.
